

Computational Data Analytics for Economists

Lecture 2

Web Scraping and Tools for Scientific Programming

Helge Liebert Anthony Strittmatter

What is this lecture about?

- Most research in economics now involves scientific programming.
- Introduce tools and ideas that may make daily research tasks easier.
- Many of these have been developed by other scientists or IT professionals.
- Some are almost as old as computers, others are novel.
- Focus is going to be on data processing.

Economics and computer science

- Data management is not taught in introductory econometrics.
- Computer science often involves processing data.
- Problems you are likely to encounter have been solved.
- CS offers tools and concepts that economists can profit from.
 - Tools: Remote servers, databases, version control, accessing APIs for data, text processing and analysis, geospatial analysis, OCR, automation, . . .
 - Concepts: Time complexity of algorithms, computational cost, databases.

Topics

- General points about scientific programming and working with computers.
- Use processing of web data to introduce various ideas along the way.
- Unix tools and the command line.
- Accessing data on the web: APIs.
- Gathering (unstructured) web data and transforming it into structured data (“*web scraping*”).
- Regular expressions.

Goal: Understanding the tools available

- Navigate the jungle: Isolating a particular tool is often harder than understanding how it works.
- Point you towards the resources and explain their general concepts.
- Methods may sometimes offer the only feasible solution to gather data.
- They may also help you solve tasks efficiently.
- Knowing that a problem can be solved and how is worth a lot.
- Leave you marginally more computer literate.

Goal: Automation

- Digitalization offers exciting data for research. But: *Data is messy*.
- Gathering or processing data often involves repetitive manual tasks.
- Disadvantages:
 - Manual tasks are often not well documented or reproducible ex post.
 - Manual work is frustrating and a huge time-sink.
 - Manual work may not be feasible with large data.

➡ Automation helps!

- Frees you to engage in other work.
- You learn new things.
- Should you encounter the same class of problem in the future, you already have a solution at hand.

Automation

Geeks and repetitive tasks

Automation

"I SPEND A LOT OF TIME ON THIS TASK.
I SHOULD WRITE A PROGRAM AUTOMATING IT!"

Example problem

- How to turn unstructured into structured data?
- Consider a situation where
 - You want to get data from the internet.
 - The data is in unstructured/semi-structured form.
 - You want to transform it into a differently structured format for further use.
 - You need to filter the available information.

From this . . .

Which language to choose?

- *Anything* can be done in *any* language. Convenience varies.
- Concepts and toolkits transfer easily most of the time.
- Trade-off: Prior knowledge vs. task suitability.
- Never re-invent the wheel.

- Choose a high-level, dynamic language. Ideally free and open source.
- Specialized languages: R, MATLAB, Octave, Gauss, Julia, . . .
- General-purpose languages: Python, Perl, Ruby, . . .
- Choice is use case- and taste-specific. Popular is typically better.

- R is the major statistical programming language.
- It is free, used in many sciences and in industry. Good documentation.
- New models are typically first published and implemented in R.
- Having data processing and analysis in the same language is nice.
- Good library support for common tools (e.g. databases, regular expressions).
- Specific tasks for which high-level wrapper functions are not available may be very cumbersome.
- In recent years, R development has been very active and libraries exist for almost anything.

Python

- General-purpose programming language, supports object-oriented programming.
- Reads like english. Explicit and clear. Whitespace matters, no braces. (*"There should be one obvious way to do it".*)
- Used extensively in industry and sciences. Good documentation.
- Libraries for almost anything.
- Many science-related libraries exist for other languages, but rarely are they as mature.
- Less support for statistical modeling (but growing).
- Less suited for interactive data work.

Recommendation

- Research ex ante which libraries are most mature and best for solving your specific problem.
- Focus on getting things done.
- Rule-of-thumb:
 - Simple data processing:
Stick with R. Augment with other tools where required.
 - More involved projects:
Go with Python. You can still analyze data in R.
- I am proposing a mix of R, Python and Bash (Unix-Shell), ... and whatever program your co-authors are using.
- R, Python and SQL are highly valued on the job market, knowing your way around a terminal is useful.
- This course uses R, but I will provide some equivalent python code.

Why not Stata, Matlab, Gauss or similar?

- Advantage: Many domain-specific models supported.
- Less support for almost anything else.
- Much less flexible for anything not to do with data analysis or numerics.
- Difficult to deploy on a server. Often tied to a GUI.
- Less popular, smaller userbase. Proprietary and expensive.
- You can still rely on them for estimation after your data is clean.

Why not Perl or Ruby?

Perl

- *“There’s more than one way to do it.”*
- Lots of special cases, reliance on hidden magic, bad readability.
- You may want to work together with somebody else.
- You may want to understand your own code in a few months time.
- Less popular in sciences.

Ruby

- Everything is an object. Really. Intuitive for some people.
- Different focus.
- Even less popular in sciences.
- Less support.

A few things to get started

- What you need for this course:
 - R.
 - A text editor or an IDE (like RStudio).
- You want to use Python:
 - A Python distribution (use Anaconda) (and possibly a shell).
 - A text editor or an IDE (like Spyder).
 - Which version, 2.7 or 3?
 - Python 3 if you plan to use Python regularly in the future.
- You want to use the command line interface (CLI) and have access to shell tools:
 - Terminal and Bash (Linux, MacOS), package manager (default on Linux, use `brew` on MacOS).
 - Cygwin, Windows Subsystem for Linux, Linux in a virtual machine, dual boot (Windows).

A note on operating systems

- MacOS or Linux offer built-in access to a Unix shell (Bash).
- Further software is managed via a package management system and distributed via software repositories.
- On Linux, use your package manager to install anything you require.
- On MacOS, familiarize yourself with Homebrew. Install `iterm2` if you want a fancier terminal.
- For Windows, many tools are not available or cumbersome to use. Dependency resolution can be a nightmare.
- Windows does not provide proper access to a Unix shell.
- Even reliably installing Python was a chore until recently (now use Anaconda.)

Command line interpreters and shells

- An interface that lets you interact with your computer.
- A CLI using a programming language that allows you to execute programs and scripts.
- Unix-based operating systems (Linux, MacOS) have Bash pre-installed.
- Windows has cmd (or PowerShell). These are not a viable replacement. Cygwin or WSL may be. Git Bash is incomplete.
- Some examples:

```
cd somedir/subdir # navigate to a folder  
cd .. # navigate to parent directory  
cd # return to your home folder  
ls # list directory contents  
R # start the R console
```
- *CTRL + c* aborts a process, *CTRL + d* quits.

Examples

- Some examples:

```
vim myscript.r # edit your R script with vim  
R -f myscript.r # execute your R script  
python myscript.py # execute your python script  
git add myscript.py # stage file for version control  
git commit myscript.py # stage file for version control  
man ssh # display manual pages for the ssh program  
ssh myusername@13.438.14.673 # secure shell login to your remote server
```

- Sounds tedious? It is. But it can also be extremely powerful.
- Convert all your pdf files in a folder to text and search them.

```
for file in *.pdf; do pdftotext "$file"; done  
grep -icr "keyword" *.txt
```

A note on text editors

- A script is a set of *plain text* instructions, fed to an interpreter.
- R scripts usually have the suffix `.r`, Python `.py`, Shell `.sh`.
- Much of our work involves working with text files.
- *Some* text editor is required. A *good* text editor makes working with text much easier and faster.
- Too many options to list. All are better than Notepad.
- A few suggestions: VS Code, Sublime Text, Atom, Notepad++.
- Learning Vim or Emacs requires you to invest some time.
- Text editors allow you to integrate your work.
- Sometimes IDEs with GUI may be more convenient.
- Features: Efficient text editing, syntax checking, completion, ...

A possible setup

```
emacs@helge-x250 ~
\begin[frame]{A note on operating systems}
\begin[Itemize]
\item MacOS or Linux offer built-in access to a Unix shell (Bash).

Examples

- Some examples:
via myscript.r # edit your R script with vim
R -f myscript.r # execute your R script
python myscript.py # execute your python script
git add myscript.py # stage file for version control
git commit myscript.py # stage file for version control
man ssh # display manual pages for the ssh program
ssh myusername@13.438.14.673 # secure shell login to your remote server
- Sounds tedious? It is. But it can also be extremely powerful.
- Convert all your pdf files in a folder to text and search them.
for file in *.pdf; do pdftotext "\$file"; done
grep -icr "keyword" *.txt

A note on text editors

- A script is a set of plain text instructions, fed to an interpreter.
- R scripts usually have the suffix .r, Python .py, Shell .sh.
- Much of our work involves working with text files.
- Some text editor is required. A good text editor makes working with text much easier and faster.
- Too many options to list. All are better than Notepad.
- A few suggestions: VS Code, Sublime Text, Atom, Notepad++.
- Learning Vim or Emacs requires you to invest some time.
- Text editors allow you to integrate your work.
- Sometimes IDEs with GUI may be more convenient.
- Features: Efficient text editing, syntax checking, completion, ...

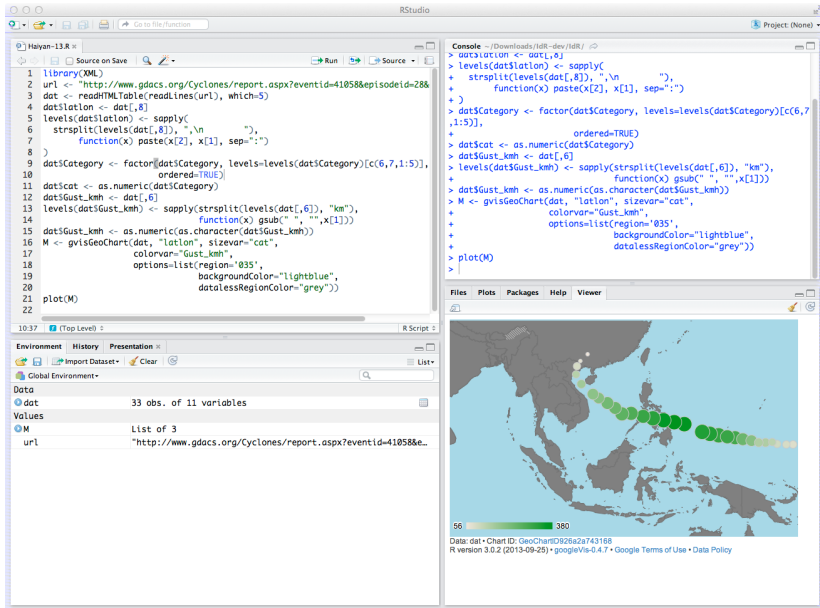

... that is universal

Version control

- Ubiquitous in IT, extremely useful in many purposes.
- Somewhat less useful for statistical data management and analysis due to different workflow. Do not version control data.
- Still good to know about and understand the basics.
- Git is the dominant version control software today.
- *ProGit* is a good and free resource. Skim the first few chapters.
- Sufficient to grasp the concept and know the basic commands.
- Lots of programs are hosted on public git repositories.

Getting started—things to consider before you begin

- Pick up the phone and try to get the data directly.
- Search if somebody has already faced the same or a similar problem.
- Does the site or service provide an API that you can access directly?
- Is there a wrapper for it?
- Is the website only online for a limited time? Do you want an original snapshot as a backup? Is it more convenient to filter your data offline?

Save an offline copy

- Use the shell utilities `wget` or `curl` to download the complete site.
- Also useful if you just want a set of files (e.g. pdf documents) from the same site directory.
- Convenient for static sites of limited size.
- Infeasible for large sites or sites that create content dynamically.

Examples

- Simple http GET request.

```
wget http://www.google.com
```

- Recursively download a website.

```
wget -r http://www.some-site.com/some-subdir/
```

- Download all pdfs from a site.

```
wget -r -A.pdf http://url-to-webpage-with-pdfs/
```

- Mirror a site offline and convert links for local browsing.

```
wget --mirror -p --convert-links -p ./local-dir  
http://target-website.com
```

Static vs. dynamic websites

Scheme A

Static Website

Scheme B

Dynamic Website

Web APIs

- Data providers often offer Web APIs (*Application Programming Interface*) to access data.
- Allow programmable access to data via a defined set of HTTP messages. Similar to visiting a website: you specify a URL and information is sent to your machine.
- With a website, you receive code interpreted by your browser (HTML, CSS, JavaScript). With an API, you receive data.
- Usually in JSON (*JavaScript Object Notation*) or XML (*Extensible Markup Language*) format.

Web APIs

- Often just two steps:
 1. Construct the URL query that serves as the API request.
 2. Process the response message the API sends back.
- Examples:
 - `https://api.kivaws.org/v1/loans/newest.html`
 - `https://api.kivaws.org/v1/loans/newest.json`
 - `https://api.kivaws.org/v1/loans/search.json?sector=Agriculture&country=VN`
 - `https://www.theyworkforyou.com/api/getMPs?&key=someapikeyhere&output=js`
- Libraries may offer wrappers for APIs: WDI, wbstats, twfy, pvsR, Google Maps, OpenStreetMap/OSRM, ...
- Sometimes it is possible to reverse engineer a site's internal API rather than scraping the HTML.

HTML and the Document Object Model

- Extracting information from the web requires a basic understanding of HTML and the associated Document Object Model (DOM).
- HTML elements provide the structure and content of web pages.
- Typically consist of `<start>` and `</end>` tags, with content in between.
`<tagname>Content here</tagname>`
- A page consists of nested elements.
- The `html` element is the outer-most element, nesting the `head` and `body` elements, which in turn have nested elements.
- Nesting structure of elements can be represented by a tree (DOM).

Document Object Model

- The DOM is a programming interface for HTML and XML documents.
- Provides a structured representation of the document.
- A document as a group of nodes, each node representing a part of the document.
- Allows programmatic access to the tree to change the structure, style and content of the document.
- Connects web pages to scripts or programming languages.

A simple HTML page

A simple HTML page:

```
<html>
  <head>
    <title>My Web Page</title>
  </head>
  <body>
    <h1>Welcome To My Web Page</h1>
  </body>
</html>
```

How a browser renders this page:

HTML and the DOM

A simple HTML page:

```
<html>
  <head>
    <title>My Web Page
  </title>
</head>
<body>
  <h1>Welcome To My Web Page
</h1>
</body>
</html>
```

Corresponding node tree:

DOM node trees

- HTML DOM views a document as a tree structure called node tree.
- Everything in an HTML document is a node.
 - The entire document is a document node
 - Every HTML element is an element node
 - Every HTML attribute is an attribute node
 - Text content in the HTML elements is a text node
- Nodes can be accessed through the tree.
- Nodes may be assigned unique id attributes.

Example: An HTML table element

- Tables are represented by a top-level table element.
- The table element nests `tr` (*table row*) elements.
- These nest `th` (*table header*) and `td` (*table data*) element cells.

HTML and the DOM

- HTML tags can have attributes and text content.

```
<tag attribute="value" attribute2="value">Text content.</tag>
```

- Example page:

```
<html>
  <head>
    <title>My Web Page</title>
  </head>
  <body>
    <h1>Welcome To My Web Page</h1>
    
    <a href="pagelink.html" id="pageid">Check this other page.</a>
  </body>
</html>
```

Data from the web

Infant mortality - Wikipedia

https://en.wikipedia.org/wiki/Infant_mortality

Government and businesses tend to show an unwillingness to these parents and their recent suffering from a lost child, and produce limited disclosures in the IMR reports that the information has not been properly reported, resulting in these discrepancies. LBIs has been done to address the underlying structural problems of the vital registry systems in respect to the lack of reporting from parents in rural areas, and in turn has created a gap between the official and popular meanings of child death.^[42] It is also argued that the bureaucratic separation of vital death recording from cultural death rituals is to blame for the inaccuracy of the infant mortality rate (IMR). Vital death registries often fail to recognize the cultural implications and importance of infant deaths. It is not to be said that vital registry systems are not an accurate representation of a region's socio-economic situation, but this is only the case if these statistics are valid, which is unfortunately not always the circumstance. "Popular death reporters" is an alternative method for collecting and processing statistics on infant and child mortality. Many regions may benefit from "popular death reporters" who are culturally linked to infants may be able to provide more accurate statistics on the incidence of infant mortality.^[43] According to ethnographic data, "popular death reporters" refers to people who had made knowledge of asphyxias, including the grave-digger, galekeeper, midwife, popular healers etc. — all key participants in customary rituals.^[44] By combining the methods of household surveys, vital registries, and asking "popular death reporters" this can increase the validity of child mortality rates, but there are many barriers that can reflect the validity of our statistics of infant mortality. One of these barriers are political economic decisions. Numbers are exaggerated when international funds are being doled out, and underrepresented during reelections.^[45]

The bureaucratic separation of vital death reporting and cultural death rituals stems in part due to structural violence.^[46] Individuals living in rural areas of Brazil need to invest large capital for lodging and travel in order to report infant birth to a Brazilian Association League office. The negative financial aspects deter registration, as often individuals are of lower income and cannot afford such expenses.^[47] Similar to the lack of birth reporting, families in rural Brazil face difficult choices based on already existing structural arrangements when choosing to report infant mortality. Financial constraints such as reliance on food supplementation may also lead to skewed infant mortality data.^[48]

In developing countries such as Brazil the inequivalent of deaths are regularly unrecorded into the countries vital registration system. This causes a skewed statistical and contextual soundness can be used to ground the meaning of mortality from a statistical standpoint. In southwest Brazil they have accomplished this standpoint while conducting an ethnographic study combined with an alternative method to survey infant mortality.^[49] These types of techniques can develop quality ethnographic data that will ultimately lead to a better portrayal of the magnitude of infant mortality in the region. Political economic reasons have been seen to slow the infant mortality data in the past when governor Costa devised his presidency campaign on reducing the infant mortality rate during his term in office. By using this new way of surveying, these instances can be minimized and removed, overall creating accurate and sound data.^[50]

Epidemiology

See also: *List of countries by infant mortality rate*

For the world, and for both less developed countries (LDCs) and more developed countries (MDCs), IMR declined significantly between 1960 and 2001. According to the *State of the World's Mothers* report by *Save the Children*, the world IMR declined from 126 in 1960 to 57 in 2001.^[141]

However, IMR was, and remains, higher in LDCs. In 2001, the IMR for LDCs (81) was about 10 times as large as it was for MDCs (8). On average, for LDCs, the IMR is 17 times as higher than that of MDCs. Also, while both LDCs and MDCs made significant reductions in infant mortality rates, reductions among less developed countries are, on average, much less than those among the more developed countries.^[142]

A factor of about 67 separate countries with the highest and lowest reported infant mortality rates. The top and bottom five countries by this measure (taken from *The World Factbook's* 2012 estimates)^[143] are shown below.

| Rank | Country | Infant mortality rate (deaths/1,000 live births) |
|------|--------------------------|--|
| 1 | Alghanistan | 131.43 |
| 2 | Niger | 103.96 |
| 3 | Mali | 109.09 |
| 4 | Somalia | 103.72 |
| 5 | Central African Republic | 97.17 |
| 218 | Sweden | 2.74 |
| 219 | Singapore | 2.66 |
| 220 | Bermuda | 2.47 |
| 221 | Japan | 2.21 |
| 222 | Monaco | 1.80 |

According to Gubler, Garland, Puleston and Szaibovich "birth histories, however, are subject to a number of errors, including omission of deaths and age misreporting errors."^[144]

United States

Of the infant mortality rate in the US decreased by 2.3% to a historic low of 562 infant death per 100,000 live births in 2014.^[145]

Of the 27 most developed countries, the U.S. has the highest Infant Mortality Rate, despite spending much more on health care per capita than *any* other nation.^[146] Significant racial and socio-economic differences in the United States affect the IMR. In contrast with other developed countries, which have more homogeneous populations. In particular, IMR varies greatly by race in the US. The average IMR for the white country is therefore not a fair representation of the wide variations that exist between segments of the population. Many theories have been explored as to why these racial differences exist with socio-economic factors usually coming out as a reasonable explanation. However, more studies have been conducted around this matter, and the largest advancement is around the idea of stress and how it affects pregnancy.^[147]

In the 1950s, the infant mortality rate in the United States was estimated at 216.6 per 1,000 babies born for whites and 346.2 per 1,000 for African Americans, but rates have significantly declined in the West in modern times. This declining rate has been due to modern improvements in basic health care, technology, and medical advances.^[148] In the last century, the infant mortality rate has decreased by 92%.^[149] Overall, the rates have decreased drastically from 20 deaths in 1970 to 6.9 deaths in 2003 per every 1,000 live births. In 2003, the leading causes of infant mortality in the United States were congenital anomalies, disorders related to immaturity, SIDS, and maternal complications. Babies born with low birth weight increased to 6.1% while cigarette smoking during pregnancy declined to 10.2%. This reflected the amount of low birth weights concluding that 12.4% of births from smokers were low birth weights compared with 1.7% of such births from non-smokers.^[150] According to *The New York Times*, "the main reason for the high rate is premature delivery, and there was a 10% increase in such births from 2000 to 2008." Between 2007 and 2011, however, the prematur birth rate has decreased every year. In 2011 there was an 11.73% rate of babies born before the 37th week of gestation, down from a high of 12.86% in 2006.^[151]

Economic expenditures on labor and delivery and neonatal care are relatively high in the United States. A conventional birth averages US\$9,775 with a C-section costing US\$15,044.^[152] Prematur births in the US have been estimated to cost \$51,800 per child, with a total yearly cost of \$26.2 billion.^[153] Despite this spending, several reports state that infant mortality rate in the United States is significantly higher than in other developed nations.^{[154][155][156]} Estimates vary; the CIA's *World Factbook* ranks the US 56th internationally in 2014, with a rate of 6.17, while the UN figures from 2005-2010 place the US 34th.

Abnormalized differences in measurement could play a substantial role in the disparity between the US and other nations. A non-viable live birth in the US could be registered as a stillbirth in similarly developed nations like Japan, Sweden, Norway, Iceland, the Netherlands, and France — thereby reducing the infant death count.^[157] Neonatal intensive care is also more likely to be applied in the US to marginally viable infants, although such interventions have been found to increase both costs and disability. A study following the implementation of the *Born Alive Infant Protection Act of 2002* found universal resuscitation of infants born between 20–25 weeks increased the neonatal spending burden by \$113.3 million while simultaneously decreasing post-natalized live births by 20%.^[158]

The vast majority of research conducted in the late twentieth and early twenty-first century indicates that African-American infants are more than twice as likely to die in their first year of life than white infants. Although following a decline from 13.63 to 11.46 deaths per 1,000 live births from 2006 to 2010, non-Hispanic black mothers continued to report a rate 2.2 times as high as that for non-Hispanic white mothers.^[114]

Contemporary research findings have demonstrated that nationwide racial disparities in infant mortality are linked to the experiential state of the mother and that these disparities cannot be totally accounted for by socio-economic, behavioral or genetic factors.^[159] The *Hispanic paradox*, an effect observed in other health indicators, appears in the infant mortality rate, as well. Hispanic mothers see an IMR comparable to non-Hispanic white mothers, despite lower educational attainment and economic status. A study in North Carolina, for example, concluded that "while women who did not complete high school have a lower infant mortality rate than black college graduates."^[160] According to Marcellio GARCIA, *Confronting Anxiety That Development in Young Adults is likely*, "self-reported experiences of racial discrimination were associated with pre-term and low-birthweight deliveries, and such experiences may contribute to black-white disparities in prenatal outcomes."^[161] Likewise, dozens of population-based studies indicate that "the subjective, or perceived experience of racial discrimination is strongly associated with an increased risk of infant death and with poor health prospects for future generations of African Americans."^[162]

World Historical and predicted Infant mortality rates per 1,000 births (1950–2050)

| Years | Rate | Years | Rate |
|-----------|------|-----------|------|
| 1950–1955 | 152 | 2000–2005 | 52 |
| 1955–1960 | 136 | 2005–2010 | 47 |

Epidemiology [edit]

See also: *List of countries by infant mortality rate*

For the world, and for both less developed countries (LDCs) and more developed countries (MDCs), IMR declined. However, IMR was, and remains, higher in LDCs. In 2001, the IMR for LDCs (91) was about 10 times as large as that for MDCs, on average, much less than those among the more developed countries.^[*clarification needed*]

A factor of about 67 separates the countries with the highest and lowest reported infant mortality rates. The top and

| Rank | Country | Infant mortality rate (deaths/1,000 live births) |
|------|--|---|
| 1 | Afghanistan | 121.63 |
| 2 | Niger | 109.98 |
| 3 | Mali | 109.08 |
| 4 | Somalia | 103.72 |
| 5 | Central African Republic | 97.17 |
| 218 | Sweden | 2.74 |
| 219 | Singapore | 2.65 |
| 220 | Bermuda | 2.47 |
| 221 | Japan | 2.21 |
| 222 | Monaco | 1.80 |

According to Guillot, Gerland, Pelletier and Saabneh "birth histories, however, are subject to a number of errors

Fetching a table from Wikipedia

```
library(rvest)

# 1) fetch and parse the website
page <- read_html("https://en.wikipedia.org/wiki/Infant_mortality")
# 2) extract the html node containing the table
table <- html_node(page,
                    xpath = "//*[@id='mw-content-text']/div/table[2]")
# 3) extract the table as a data frame
mrates <- html_table(table)
```

Inspecting the HTML source

- Convenient with modern browsers: Use the developer tools.
- Right-click *Inspect* (for Chrome there is also SelectorGadget).
- Look at the HTML source to grasp the structure.
- Find out how to navigate the site.
- Find the element(s) you want to extract.
- Get the Xpath expression or CSS selector to extract elements.

Epidemiology [edit]

See also: *List of countries by infant mortality rate*

For the world, and for both less developed countries (LDCs) and more developed countries (MDCs), IMR declined significantly between 1960 and 2001. According to the [State of the World's Mothers report](#) by [Save the Children](#), the world IMR declined from 126 in 1960 to 57 in 2001.^[10]

However, IMR was, and remains, higher in LDCs. In 2001, the IMR for LDCs (91) was about 10 times as large as it was for MDCs (8). On average, for LDCs, the IMR is 17 times as higher than that of MDCs. Also, while both LDCs and MDCs made significant reductions in infant mortality rates, reductions among less developed countries are, on average, much less than those among the more developed countries. [\[identification needed\]](#)

A factor of about 67 separate countries with the highest and lowest reported infant mortality rates. The top and bottom five countries by this measure (taken from [The World Factbook's](#) 2012

table.wikitable | 380 x 320

| Rank | Country | Infant mortality rate (deaths/1,000 live births) |

| 219 | Singapore | 2.65 |
| 220 | Bermuda | 2.47 |
| 221 | Japan | 2.21 |
| 222 | Monaco | 1.80 |

According to Guillot, Gerland, Pelffeter and Saabneh "birth histories, however, are subject to a number of errors, including omission of deaths and age misreporting errors."¹⁰³

United States [[edit](#)]

The infant mortality rate in the US decreased by 2.3% to a historic low of 582 infant deaths per 100,000 live births in 2014.^[104]

Of the 27 most developed countries, the U.S. has the highest Infant Mortality Rate, despite spending much more on health care per capita ^(data not needed). Significant racial and socio-economic differences in the United States affect the IMR, in contrast with other developed countries, which have more homogeneous populations. In particular, IMR varies greatly by race in the US. The average IMR for the whole country is therefore not a fair representation of the wide variations that exist between segments of the population. Many theories have been explored as to why these racial differences exist.

Infant mortality rates from Wikipedia

```
<table class="wikitable" style="text-align:left">
  <tbody>
    <tr>
      <th>Rank</th>
      <th>Country</th>
      <th>Infant mortality rate <br> (deaths/1,000 live births)</th>
    </tr>
    <tr>
      <td>1</td>
      <td style="text-align:left;"><a href="/wiki/Afghanistan" title="Afghanistan">Afghanistan</a></td>
      <td>121.63</td>
    </tr>
    <tr>
      <td>2</td>
      <td style="text-align:left;"><a href="/wiki/Niger" title="Niger">Niger</a></td>
      <td>109.98</td>
    </tr>
    <tr>
      <td>3</td>
      <td style="text-align:left;"><a href="/wiki/Mali" title="Mali">Mali</a></td>
      <td>109.08</td>
    </tr>
    <tr>
      <td>4</td>
      <td style="text-align:left;"><a href="/wiki/Somalia" title="Somalia">Somalia</a></td>
      <td>103.72</td>
    </tr>
    ...
  </tbody>
</table>
```

Fetching a table from Wikipedia

```
# fetch and parse the website
page <- read_html("https://en.wikipedia.org/wiki/Infant_mortality")
# list the table nodes
html_nodes(page, "table")
# using xpath expressions or css selectors is equivalent
table <- html_node(page,
                    xpath = "//*[@id='mw-content-text']/div/table[2]")
table <- html_node(page,
                    css = "#mw-content-text > div > table:nth-child(121)")
```

The general structure

- There is no universal recipe. But most programs follow a certain structure.
 1. Open a website mimicking a browser and navigate it (optional).
 2. Get the page source HTML and feed it to a parser.
 3. Extract the elements you need.
 4. Filter and arrange them as needed and save them.
 5. Repeat 1.–4. until you have everything you want.
 6. Output your data.

Navigating to another page

```
# Open infant mortality page
session <- html_session("https://en.wikipedia.org/wiki/Infant_mortality")
# Goto page on Somalia
session <- follow_link(session, "Somalia")
# Read the source
page <- read_html(session)
# Extract html
table <- html_node(page,
                    xpath = "//*[@id='mw-content-text']/div/table[4]")
regions <- html_table(table)
```

Filtering links

```
# read wiki page
page <- read_html("https://en.wikipedia.org/wiki/Infant_mortality")
# get the links
wikilinks <- html_attr(html_nodes(page, "a"), "href")
# use regex to filter internal links:
#   select only articles, no files or category pages,
#   matching with mortality or somalia
links <- grep("^(!.*:)(/wiki/. *Mortality)|(/wiki/. *Somalia)", wikilinks,
              ignore.case = TRUE, value = TRUE, perl = TRUE)
links <- unique(links)
# go to first selected article page and process it
session <- jump_to(session, links[1])
page <- read_html(session)
html_nodes(page, "title")
```

Regular expressions

- Regular expressions are character sequences defining a search pattern.
- Usually used for find/replace operations on strings, or for validation.
- Regexes are an *extremely* helpful tool.
- Easy to grasp, complex to master.
- Pin a cheatsheet to your office wall.
- But: Regular expressions are not parsers. Always use a dedicated HTML parser to extract elements.

Regular expressions

General remarks

- Start simple and expand your program incrementally.
- Keep it simple. Do not overengineer the problem.
- Do not repeat yourself. Code duplication implies bug reuse.
- Limit the number of iterations for test runs. Use print statements to inspect objects.
- Write tests to verify things work as intended.
- If the web page cannot be navigated easily or has hidden javascript, look into Selenium (`library(rselenium)`).
- If you scraper requires complex monitoring/validation procedures or threading for performance, look into Python.

Assignment

- Phillippine Statistics Authority *Good Governance Index*.
- Available at <http://nap.psa.gov.ph/ggi/default.asp>.
- Get all GGI data tables for all municipalities.
- Save them in a local data file for further analysis.
- Try for yourself. How would you go about this?

Assignment

- Submission deadline is next Monday, January 28.
- Submit code only, no data.
- Comment your code or submit a short description alongside explaining it.
- A proof-of-concept restricted to the first 30 municipalities is fine.
- Accounts for 20% of the final grade.

Final remarks

- Sometimes small programs can go a long way.
- Do not lose sight of your ultimate goal. Time is valuable.
- Do not engage in perfectionism, focus on GTD.
- Identify everyday tasks that you can optimize.
- It might even be fun.

Appendix

Why Python?

```
>>> import this
```

The Zen of Python, by Tim Peters

```
Beautiful is better than ugly.  
Explicit is better than implicit.  
Simple is better than complex.  
Complex is better than complicated.  
Flat is better than nested.  
Sparse is better than dense.  
Readability counts.  
Special cases aren't special enough to break the rules.  
Although practicality beats purity.  
Errors should never pass silently.  
Unless explicitly silenced.  
In the face of ambiguity, refuse the temptation to guess.  
There should be one-- and preferably only one --obvious way to do it.  
Although that way may not be obvious at first unless you're Dutch.  
Now is better than never.  
Although never is often better than *right* now.  
If the implementation is hard to explain, it's a bad idea.  
If the implementation is easy to explain, it may be a good idea.  
Namespaces are one honking great idea -- let's do more of those!  
>>>
```

What (else) can Python be used for?

- Almost anything you can do in Stata, R, Gauss, Matlab or similar software. Library support is growing.
- Data management, analysis, numerics, graphs, structural modelling etc. (e.g. `scipy`, `pandas`, `numpy`, `matplotlib`, `seaborn`).
- Symbolic math (e.g. `sympy`, Sage).
- Geospatial work (e.g. QGIS).
- Text analysis and language processing (e.g. `nltk`, `spacy`, `gensim`).
- Create a website or blog (e.g. `django`, `hyde`, `sphinx`).
- Directly access many APIs (e.g. Twitter).
- Automate pretty much anything (e.g. experiments, data collection).
- In recent years, R has been extended to many of these domains.

Python resources

- Relevant modules.
 - requests, bs4/BeautifulSoup, mechanize/mechanicalsoup, selenium
 - Scrapy provides a complete framework for more complex projects.
 - csv, re, pickle, pprint, pandas, random, itertools, pickle, ...
- Learning the language.
 - *A byte of Python* is free. *The Quick Python Book* or *Dive into Python* offer a denser treatment.
 - O'Reilly: *Learning Python/Programming Python/Pocket reference, Web scraping with Python*.
 - *Automate the boring stuff with Python* for inspiration.
 - Plenty of video lectures and courses online. Stackoverflow helps.
 - (For Git: *ProGit* is free and really all you need.)
- Read about basic types, syntax, look at a few examples, then just have a go.
